

Sustainability of Rice production; Is Aerobic rice the way forward

**Mohd Yusoff A., Nurnabihah H., Nora Ashikin A & Hermah Muhasaffia H.
Fac. of Plantation & Agrotechnology, UiTM**

Presentation Outline

- ✚ Sustainability in relation to global challenges
- ✚ GHG emission from agriculture Global Scenario (AR5-FAO, 2014)
- ✚ GHG emission from agriculture Malaysian Scenario (NC2, year 2000)
- ✚ Carbon foot print – Case study
- ✚ Aerobic rice – mitigating GHG emission

Global Challenges

Food Security

Climate change

**Agri-Food
System**

Food & Health

Biobased
Economy

Agriculture & Climate Change

- Agriculture plays a dual role in global efforts to reduce the greenhouse gas (GHG) emissions that contribute to climate change.
- First, the agriculture is a major source of GHG emissions.
- Second, the agricultural sector provides major opportunities for the mitigation of GHGs.

Agriculture's GHG emissions on the rise

- FAO global estimates of GHG data show that emissions from agriculture, forestry and fisheries have nearly doubled over the past fifty years and could increase an additional 30 percent by 2050, without proper mitigation. (IPCC-AR5)
- Agricultural emissions from crop and livestock production grew from 4.7 billion tonnes of CO₂ eq in 2001 to over 5.3 billion tonnes in 2011, a 14 % increase.
- Sources of agricultural emissions-2011; 1. Enteric fermentation (39%), 2. Synthetic fertilizers (13%) & 3. Rice cultivation (10%)

Range of Yield Change as affected by climate change

IPCC AR5

Agriculture and GHG Emission

- Rice cultivation - Greenhouse gas emissions from rice cultivation consist of methane, CH₄, produced from the anaerobic decomposition of organic matter in paddy fields.
- **Synthetic fertilizers** ; Greenhouse gas emissions from synthetic fertilizers consist of nitrous oxide from synthetic nitrogen added to managed soils.

Trends of GHG emissions from Agriculture-AR5

IPCC AR5

Agriculture; Emissions by sector (1990 – 2012)

GHG Emission from Malaysian Agriculture 1990-2012

Methane (CH₄) emission from rice cultivation fields

CH₄ emitted by anaerobic decomposition of organic matter in paddy fields

GHG emission from Synthetic fertilizers in Malaysia

Second National Communication to the UNFCCC

M A L A Y S I A

Major Sources of CH₄ Emissions

1. Landfill
2. Fugitive emission O&G
3. Rice production
4. Industrial
5. Enteric
6. Others

Major Sources of NO₂ Emissions

GHG	Emissions (Gg)	GWP	CO ₂ eq (Gg)
CH ₄	153.33	21	3,220
N ₂ O	8.66	310	2,686
Total			5,906

Mitigation Options In The Rice Management

Mitigation technology options and practices,

GHG	Technology/Practice	Technical Mitigation Potential	Ease of Implementation (acceptance or adoption by land manager):	Timescale for Implementation
C	Straw retention	Medium	High	Available
CH ₄ :	Water management, mid-season paddy drainage	High	Medium	Available
N ₂ O:	Water management, N fertilizer application rate,	Low	High	Available

FAO DATA; Methodology and Quality Information

- GHG emissions from rice cultivation consist of methane gas (CH₄) emitted by anaerobic decomposition of organic matter in paddy fields. The FAOSTAT data are computed at Tier 1 following IPCC, 1997 Vol. 3, Ch. 4 and IPCC, 2000, Ch. 4.
- The emissions are estimated at country level, using the formula:
Emission = A * EF
 - where: Emission = GHG emissions in g CH₄ m⁻² yr⁻¹ ;
 - A = Activity data, representing rice paddy annual harvested area in m⁻² (1);
 - EF = Tier 1, default IPCC emission factors, in g CH₄ m⁻² yr⁻¹ (2).

- Assessment of land use sustainability and management system must address current global issues i.e.
 - Emission of GHGs from agricultural practices
 - Food security
- The accelerated greenhouse effect,
- In relation to soil and environmental degradation.
- Reducing emissions implies enhancing use efficiency of all these inputs by decreasing losses, and using other **C-efficient alternatives**

Carbon footprint

- The carbon footprint is a measure of the exclusive total amount of carbon dioxide emissions that is directly and indirectly caused by an activity or is accumulated over the life stages of a product.“
- **Carbon footprint can be defined as the amount of CO₂ and other GHG produced through full life cycle of a process or product ”** (Parliamentary Office of science and technology. POST, 2006).
- Carbon footprint is express in unit of **carbon equivalent** (CE)

Carbon labelling

Case Study

Case Study-Objectives

- To assess carbon emission in relation to farming system in selected rice production systems (MADA, KADA, SRI-Seberang Perak).
- To determine differences in GHGs emissions between conventional and organic practices of rice cultivation
- Agronomic practices that most contribute to carbon emission.

Agronomic practices – GHG Emissions

The total CO₂ emission from various cultural practices were grouped into six stages of rice growth.

Land preparation

Field establishment

Tillering

Heading

Ripening

Harvesting

- Mechanization
- Fertilization
- Crop protection
- Miscellaneous

The inputs requirement for each stage varies with the crop requirement hence \sum C emission differs according to stage.

Agronomic practices – Cropping stages

Paddy crop stages	Activities
Land Preparation	Land clearing, herbicide, liming, tillage, soil conditioner, fungicide, molluscicide and rodenticide
Field establishment	Seed broadcasting, herbicide, molluscicide and rodenticide
Tillering	Fertilization, fungicide, insecticide and rodenticide
Active tillering	Fertilization, fungicide and insecticide
Panicle initiation	Fertilizer and rodenticide
Flowering	Fungicide and insecticide
Grain filling	Fertilization, fungicide and insecticide
Ripening & harvesting	Insecticide and farm machinery

Methodology- Calculation of CE

- Carbon footprint value (kg CE) was calculated by using formula:-

$$\begin{array}{ccc} \text{Agricultural input} & \times & \text{Emission factor (EF)} \\ \text{(Unit)} & & \text{(literature)} \end{array}$$

- Agricultural input is the total amount of input used by each agronomic practices.
- EF is the total of carbon that emit when applied each of the farming activities.**

Mechanization

Units of machineries use x EF (kg CE/ha) = CO₂ eq/ha.

Eg: 1 unit of rotary tiller x 15.2 = 15.2 kg CE/ha

Fertilization

Rate of application (kg/ha) x EF (kg CE/ha) = CO₂ eq/ha.

Eg: 46% N with 83.33 kg/ha rate of application; $46/100 \times 83.33 \times 1.35 = 51.75$ kg CE/ha

Pesticides

Rate of application (kg/ha) x EF (kg CE/ha) = CO₂ eq/ha.

Eg: Glyphosate with 1.25 lt/ha rate of application $1.25 \times 9.1 = 11.37$ kg CE/ha

Methodology- Calculation of CE

- Emission factor used by using Tier 1, 2 and 3 approach.
- Depends on availability specification of emission factor.

Carbon Footprint = \sum CO₂ eq. of all inputs (Dubey,2008)

Tier	Specification	Emission factor
01	Pesticide	6.3 kg CE/kg
02	Fungicide	3.9 kg CE/kg
03	Benomyl	8.0 kg CE/kg a.i.)

← More accurate

Climate Smart Agriculture

Climate Smart Agriculture

Agriculture that sustainably:

1. Increases **productivity**

2. **Resilience** (adaptation)

3. Reduces **GHG**

(mitigation) and enhances achievement of national **food security** and **development goals** (FAO, 2010)-

(www.fao.org/climatechange/climatesmart/en)

Food Security

Ecological
foot print

Adaptation

Climate smart means landscape and policy smart

- A slogan for sustainable agriculture: 'Mot Phai, Nam Giam' rice production
- A catch phrase for a climate-smart way to produce rice has shown small farmers how they can boost rice profitability, while also reducing greenhouse gas emissions – World Bank.

Aerobic Rice

MARDI Aerob 1

- Water saving technology
- Climate change mitigation

Options that mitigate GHG emissions

- Irrigation patterns,
- Modifying tillage permutations
- Managing organic and fertilizer inputs,
- Selecting suitable cultivar,
- Cropping regime
-

Modifying irrigation pattern

Relative mitigation potential (GHG emissions) of various water management practices as compared to traditional flooding in rice

- Intermittent irrigation
 - Mid-season drainage
 - Multiple drainage
 - Controlled irrigation
 - Alternate wetting and drying
 - No flooding (wet)
-
- Mitigate: CH₄, N₂O
 - Mitigation potential ; varies from as low as 15%- 73%

Source: (Hussain S et al 2015.

Modifying tillage permutations

- Generally reducing tillage and soil disturbance in rice-based cropping systems could lead to less GHG emissions
- The field CO₂ fluxes after crop harvest generally lesser under no tillage than conventional tillage
- CH₄ emissions reduction under NT could be due to the increase in soil bulk density resulting in decrease volume fraction of large pores and less decomposition of organic matter
- The effects of NT on N₂O emission gave diverse results
- NT practices are capable of offsetting overall GHG emissions because of C sequestration and CH₄ mitigation ability.
- Overall GWP of NT is less than CT in rice fields

Conventional (CT) and no-till (NT) practices on GHG emissions in rice

	CH ₄ (kg ha ⁻¹)	N ₂ O (kg ha ⁻¹)	CO ₂ (kg ha ⁻¹)	Reference
NT	279	–	–	Ali et al. (2009)
CT	381	–	–	
NT	188.1	0.51	–	Zhang et al. (2013)
CT	228.3	0.43	–	
NT	297.0	–	10,553.0	Li et al. (2013)
CT	721.5	–	16,328.5	

The adoption of NT is beneficial in GHG mitigation and C-smart agriculture and needs to be promoted in rice-based cropping systems.

Managing organic additives

- Field straw removal is an effective measure reducing GHG emission of all three gases as compared with straw incorporation
- In the long run with reduction in organic manure application; rice soils need straw recycling to overcome C losses due to soil cultivation and crop harvesting.

Fertilizer management

- Enhancing the fertilizer use efficiency can reduce GHG emissions especially N₂O and it can also indirectly minimize CO₂ emissions from manufacturing of nitrogenous fertilizer
- Selected suggested fertilizer management that can reduce GHG emissions from rice field
 - Site specific nutrient management (NO₂, CH₄, CO₂)
 - Adjustment on rate, placement and application time (4R concept) (NO₂, CH₄)
 - Slow release fertilizers & nitrification inhibitors (NO₂, CH₄)

Looking for the right rice cultivar

- Breeding is always a promising strategy to minimize GHG emissions particularly CH₄.
- The target - selection of less CH₄ emitting and N responsive cultivar that will minimise CH₄ and NO₂ emissions
- Taking advantage of cultivars variabilities (gene bank) on the basis of morphological and physiological traits and adaptation to a wide range of environmental parameters.

Looking for the right rice cultivar

- Assessment and selection on the following aspects;
 - Cultivars variations in CH₄ emission - variation in CH₄ production, oxidation, and transport capacities.
 - Soil redox potential (Eh) controls the CH₄ production rate of rice soils, with a specific threshold level.
 - Root respiration and exudation influence soil redox potential (Eh)
 - Overall growth development; aboveground biomass, plant development over the entire rice growing season will influence Eh
 - Cultivars with stronger root system can release more oxygen into the soil, enhance resistance to environmental stresses, and increase crop yield

Rice Gene Bank

CONCLUSION

- Information on increasing trend of GHG emissions under conventional rice cultivation under *Business As Usual scenario* is plenty and real
- Most of the available technologies on mitigating GHG are ready for the adoption
- Policy intervention maybe needed.
- Aerobic rice is the production system for water scarce environment and changing climate
